

## Z8400/Z84C00 NMOS/CMOS Z80® CPU Central Processing Unit

### FEATURES

The extensive instruction set contains 158 instructions, including the 8080A instruction set as a subset.

- NMOS version for low cost high performance solutions, CMOS version for high performance low power designs.
- NMOS Z8400004 - 4 MHz, Z8400006 - 6.17 MHz, Z8400008 - 8 MHz.
- CMOS Z84C0006 - DC to 6.17 MHz, Z84C0008 - DC to 8 MHz, Z84C0010 - DC to 10 MHz, Z84C0020 - DC to 20 MHz
- 8 MHz version can be operated at 6.144 MHz clock.

- The Z80 microprocessors and associated family of peripherals can be linked by a vectored interrupt system. This system can be daisy-chained to allow implementation of a priority interrupt scheme.
- Duplicate set of both general-purpose and flag registers.
- Two sixteen-bit index registers.
- Three modes of maskable interrupts:  
Mode 0—8080A similar;  
Mode 1—Non-Z80 environment, location 38H;  
Mode 2—Z80 family peripherals, vectored interrupts.
- On-chip dynamic memory refresh counter.

## GENERAL DESCRIPTION

The CPUs are fourth-generation enhanced microprocessors with exceptional computational power. They offer higher system throughput and more efficient memory utilization than comparable second- and third-generation microprocessors. The internal registers contain 208 bits of read/write memory that are accessible to the programmer. These registers include two sets of six general-purpose registers which may be used individually as either 8-bit registers or as 16-bit register pairs. In addition, there are two sets of accumulator and flag registers. A group of "Exchange" instructions makes either set of main or alternate registers accessible to the programmer. The alternate set allows operation in foreground-background mode or it may be reserved for very fast interrupt response.

The CPU also contains a Stack Pointer, Program Counter, two index registers, a Retresh register (counter), and an Interrupt register. The CPU is easy to incorporate into a system since it requires only a single +5V power source. All output signals are fully decoded and timed to control standard memory or peripheral circuits; the CPU is supported by an extensive family of peripheral controllers. The internal block diagram (Figure 3) shows the primary functions of the processors. Subsequent text provides more detail on the I/O controller family, registers, instruction set, interrupts and daisy chaining, and CPU timing.

**Figure 3. Z80C CPU Block Diagram**

Table 1. Z80C CPU Registers

Register		Size (Bits)	Remarks
A, A'	Accumulator	8	Stores an operand or the results of an operation.
F, F'	Flags	8	See Instruction Set.
B, B'	General Purpose	8	Can be used separately or as a 16-bit register with C.
C, C'	General Purpose	8	Can be used separately or as a 16-bit register with B.
D, D'	General Purpose	8	Can be used separately or as a 16-bit register with E.
E, E'	General Purpose	8	Can be used separately or as a 16-bit register with D.
H, H'	General Purpose	8	Can be used separately or as a 16-bit register with L.
L, L'	General Purpose	8	Can be used separately or as a 16-bit register with H.
Note: The (B,C), (D,E), and (H,L) sets are combined as follows.			
		B — High byte	C — Low byte
		D — High byte	E — Low byte
		H — High byte	L — Low byte
I	Interrupt Register	8	Stores upper eight bits of memory address for vectored interrupt processing.
R	Refresh Register	8	Provides user-transparent dynamic memory refresh. Automatically incremented and placed on the address bus during each instruction fetch cycle.
IX	Index Register	16	Used for indexed addressing.
IY	Index Register	16	Used for indexed addressing.
SP	Stack Pointer	18	Holds address of the top of the stack. See Push or Pop in instruction set.
PC	Program Counter	16	Holds address of next instruction.
IFF <sub>1</sub> -IFF <sub>2</sub>	Interrupt Enable	Flip-Flops	Set or reset to indicate interrupt status (see Figure 4).
IMFa-IMFb	Interrupt Mode	Flip-Flops	Reflect Interrupt mode (see Figure 4).

failure has been detected. After recognition of the  $\overline{\text{NMI}}$  signal (providing  $\overline{\text{BUSREQ}}$  is not active), the CPU jumps to restart location 0066H. Normally, software starting at this address contains the interrupt service routine.

**Maskable Interrupt ( $\overline{\text{INT}}$ ).** Regardless of the interrupt mode set by the user, the CPU response to a maskable interrupt input follows a common timing cycle. After the interrupt has been detected by the CPU (provided that interrupts are enabled and  $\overline{\text{BUSREQ}}$  is not active) a special interrupt processing cycle begins. This is a special fetch ( $\overline{\text{M1}}$ ) cycle in which  $\overline{\text{IORQ}}$  becomes active rather than  $\overline{\text{MREQ}}$ , as in a normal  $\overline{\text{M1}}$  cycle. In addition, this special  $\overline{\text{M1}}$  cycle is automatically extended by two  $\overline{\text{WAIT}}$  states, to allow for the time required to acknowledge the interrupt request.

**Mode 0 Interrupt Operation.** This mode is similar to the 8080 microprocessor interrupt service procedures. The interrupting device places an instruction on the data bus. This is normally a Restart instruction, which will initiate a call

to the selected one of eight restart locations in page zero of memory. Unlike the 8080, the Z80 CPU responds to the Call instruction with only one interrupt acknowledge cycle followed by two memory read cycles.

**Mode 1 Interrupt Operation.** Mode 1 operation is very similar to that for the  $\overline{\text{NMI}}$ . The principal difference is that the Mode 1 interrupt has only one restart location, 0038H.

**Mode 2 Interrupt Operation.** This interrupt mode has been designed to most effectively utilize the capabilities of the Z80 microprocessor and its associated peripheral family. The interrupting peripheral device selects the starting address of the interrupt service routine. It does this by placing an 8-bit vector on the data bus during the interrupt acknowledge cycle. The CPU forms a pointer using this byte as the lower 8 bits and the contents of the I register as the upper 8 bits. This points to an entry in a table of addresses for interrupt service routines. The CPU then jumps to the routine at that

address. This flexibility in selecting the interrupt service routine address allows the peripheral device to use several different types of service routines. These routines may be located at any available location in memory. Since the interrupting device supplies the low-order byte of the 2-byte vector, bit 0 ( $A_0$ ) must be a zero.

**Interrupt Enable/Disable Operation.** Two flip-flops, IFF<sub>1</sub> and IFF<sub>2</sub>, referred to in the register description, are used to signal the CPU interrupt status. Operation of the two flip-flops is described in Table 2. For more details, refer to the *Z80 CPU Technical Manual* (03-0029-01) and *Z80 Assembly Language Programming Manual* (03-0002-01).

Table 2. State of Flip-Flops

Action	IFF <sub>1</sub>	IFF <sub>2</sub>	Comments
CPU Reset	0	0	Maskable interrupt INT disabled
DI instruction execution	0	0	Maskable interrupt INT disabled
EI instruction execution	1	1	Maskable interrupt INT enabled
LD A,I instruction execution	•	•	IFF <sub>2</sub> → Parity flag
LD A,R instruction execution	•	•	IFF <sub>2</sub> → Parity flag
Accept NMI	0	•	Maskable interrupt INT disabled
RETN instruction execution	IFF <sub>2</sub>	•	IFF <sub>2</sub> → IFF <sub>1</sub> at completion of an NMI service routine.

## INSTRUCTION SET

The microprocessor has one of the most powerful and versatile instruction sets available in any 8-bit microprocessor. It includes such unique operations as a block move for fast, efficient data transfers within memory, or between memory and I/O. It also allows operations on any bit in any location in memory.

The following is a summary of the instruction set which shows the assembly language mnemonic, the operation, the flag status, and gives comments on each instruction. For an explanation of flag notations and symbols for mnemonic tables, see the Symbolic Notations section which follows these tables. The *Z80 CPU Technical Manual* (03-0029-01), the *Programmer's Reference Guide* (03-0012-03), and *Assembly Language Programming Manual* (03-0002-01) contain significantly more details for programming use.

The instructions are divided into the following categories:

- ☐ 8-bit loads
- ☐ 16-bit loads
- ☐ Exchanges, block transfers, and searches
- ☐ 8-bit arithmetic and logic operations
- ☐ General-purpose arithmetic and CPU control
- ☐ 16-bit arithmetic operations
- ☐ Rotates and shifts

- ☐ Bit set, reset, and test operations
- ☐ Jumps
- ☐ Calls, returns, and restarts
- ☐ Input and output operations

A variety of addressing modes are implemented to permit efficient and fast data transfer between various registers, memory locations, and input/output devices. These addressing modes include:

- ☐ Immediate
- ☐ Immediate extended
- ☐ Modified page zero
- ☐ Relative
- ☐ Extended
- ☐ Indexed
- ☐ Register
- ☐ Register indirect
- ☐ Implied
- ☐ Bit

INC (IY+d)	(IY+d) $\leftarrow$ (IY+d) + 1	†	†	X	†	X	V 0 •	11 111 101 00 110 100	FD	3	6	23	
								$\leftarrow d \rightarrow$					
DEC m	$m \leftarrow m - 1$	†	†	X	†	X	V 1 •	101					

NOTE: m is any of r, (HL), (IX+d), (IY+d) as shown for INC. DEC same format and states as INC. Replace 100 with 101 in opcode.

## GENERAL-PURPOSE ARITHMETIC AND CPU CONTROL GROUPS

Mnemonic	Symbolic Operation	S	Z	Flags H	P/V	N	C	Opcode 76 543 210	Hex	No. of Bytes	No. of M Cycles	No. of T States	Comments
DAA	@	†	†	X	†	X	P • †	00 100 111	27	1	1	4	Decimal adjust accumulator.
CPL	$A \leftarrow A$	•	•	X	1	X	• 1 •	00 101 111	2F	1	1	4	Complement accumulator (one's complement).
NEG	$A \leftarrow 0 - A$	†	†	X	†	X	V 1 †	11 101 101 01 000 100	ED 44	2	2	8	Negate acc. (two's complement).
CCF	$CY \leftarrow CY$	•	•	X	X	X	• 0 †	00 111 111	3F	1	1	4	Complement carry flag.
SCF	$CY \leftarrow 1$	•	•	X	0	X	• 0 1	00 110 111	37	1	1	4	Set carry flag.
NOP	No operation	•	•	X	•	X	• • •	00 000 000	00	1	1	4	
HALT	CPU halted	•	•	X	•	X	• • •	01 110 110	76	1	1	4	
DI ★	$IFF \leftarrow 0$	•	•	X	•	X	• • •	11 110 011	F3	1	1	4	
EI ★	$IFF \leftarrow 1$	•	•	X	•	X	• • •	11 111 011	FB	1	1	4	
IM 0	Set interrupt mode 0	•	•	X	•	X	• • •	11 101 101 01 000 110	ED 46	2	2	8	
IM 1	Set interrupt mode 1	•	•	X	•	X	• • •	11 101 101 01 010 110	ED 56	2	2	8	
IM 2	Set interrupt mode 2	•	•	X	•	X	• • •	11 101 101 01 011 110	ED 5E	2	2	8	

NOTES: @ converts accumulator content into packed BCD following add or subtract with packed BCD operands.  
 IFF indicates the interrupt enable flip-flop.  
 CY indicates the carry flip-flop.  
 ★ indicates interrupts are not sampled at the end of EI or DI.

## 16-BIT ARITHMETIC GROUP

## SUMMARY OF FLAG OPERATION

Instructions	D <sub>7</sub>	S	Z	H	P/V	N	D <sub>0</sub>	C	Comments
ADD A, s; ADC A, s	†	†	X	†	X	V	0	†	8-bit add or add with carry.
SUB s; SBC A, s; CP s; NEG	†	†	X	†	X	V	1	†	8-bit subtract, subtract with carry, compare and negate accumulator.
AND s	†	†	X	1	X	P	0	0	Logical operation.
OR s; XOR s	†	†	X	0	X	P	0	0	Logical operation.
INC s	†	†	X	†	X	V	0	•	8-bit increment.
DEC s	†	†	X	†	X	V	1	•	8-bit decrement.
ADD DD, ss	•	•	X	X	X	•	0	†	16-bit add.
ADC HL, ss	†	†	X	X	X	V	0	†	16-bit add with carry.
SBC HL, ss	†	†	X	X	X	V	1	†	16-bit subtract with carry.
RLA; RLCA; RRA; RRCA	•	•	X	0	X	•	0	†	Rotate accumulator.
RL m; RLC m; RR m;	†	†	X	0	X	P	0	†	Rotate and shift locations.
RRC m; SLA m;									
SRA m; SRL m									
RLD; RRD	†	†	X	0	X	P	0	•	Rotate digit left and right.
DAA	†	†	X	†	X	P	•	†	Decimal adjust accumulator.
CPL	•	•	X	1	X	•	1	•	Complement accumulator.
SCF	•	•	X	0	X	•	0	1	Set carry.
CCF	•	•	X	X	X	•	0	†	Complement carry.
IN r(C)	†	†	X	0	X	P	0	•	Input register indirect.
INI; IND; OUTI; OUTD	X	†	X	X	X	X	1	•	Block input and output. Z = 1 if B ≠ 0, otherwise Z = 0.
INIR; INDR; OTIR; OTDR	X	1	X	X	X	X	1	•	Block input and output. Z = 1 if B ≠ 0, otherwise Z = 0.
LDI; LDD	X	X	X	0	X	†	0	•	Block transfer instructions. P/V = 1 if BC ≠ 0, otherwise P/V = 0.
LDIR; LDDR	X	X	X	0	X	0	0	•	Block transfer instructions. P/V = 1 if BC ≠ 0, otherwise P/V = 0.
CPI; CPIR; CPD; CPDR	X	†	X	X	X	†	1	•	Block search instructions. Z = 1 if A = (HL), otherwise Z = 0. P/V = 1 if BC ≠ 0, otherwise P/V = 0.
LDA; I, LD A, R	†	†	X	0	X	IFF	0	•	IFF, the content of the interrupt enable flip-flop, (IFF <sub>2</sub> ), is copied into the P/V flag.
BIT b, s	X	†	X	1	X	X	0	•	The state of bit b of location s is copied into the Z flag.

## SYMBOLIC NOTATION

Symbol	Operation	Symbol	Operation
S	Sign flag. S = 1 if the MSB of the result is 1.	†	The flag is affected according to the result of the operation.
Z	Zero flag. Z = 1 if the result of the operation is 0.	•	The flag is unchanged by the operation.
P/V	Parity or overflow flag. Parity (P) and overflow (V) share the same flag. Logical operations affect this flag with the parity of the result while arithmetic operations affect this flag with the overflow of the result. If P/V holds parity: P/V = 1 if the result of the operation is even; P/V = 0 if result is odd. If P/V holds overflow, P/V = 1 if the result of the operation produced an overflow. If P/V does not hold overflow, P/V = 0.	0	The flag is reset by the operation.
H*	Half-carry flag. H = 1 if the add or subtract operation produced a carry into, or borrow from, bit 4 of the accumulator.	1	The flag is set by the operation.
N*	Add/Subtract flag. N = 1 if the previous operation was a subtract.	X	The flag is indeterminate.
C	Carry/Link flag. C = 1 if the operation produced a carry from the MSB of the operand or result.	V	P/V flag affected according to the overflow result of the operation.
		P	P/V flag affected according to the parity result of the operation.
		r	Any one of the CPU registers A, B, C, D, E, H, L.
		s	Any 8-bit location for all the addressing modes allowed for the particular instruction.
		ss	Any 16-bit location for all the addressing modes allowed for that instruction.
		ii	Any one of the two index registers IX or IY.
		R	Refresh counter.
		n	8-bit value in range < 0, 255 >.
		nn	16-bit value in range < 0, 65535 >.

\* H and N flags are used in conjunction with the decimal adjust instruction (DAA) to properly correct the result into packed BCD format following addition or subtraction using operands with packed BCD format.

## CPU REGISTERS

Figure 4 shows three groups of registers within the CPU. The first group consists of duplicate sets of 8-bit registers: a principal set and an alternate set [designated by ' (prime), e.g., A<sup>1</sup>]. Both sets consist of the Accumulator register, the Flag register, and six general-purpose registers. Transfer of data between these duplicate sets of registers is accomplished by use of "Exchange" instructions. The result is faster response to interrupts and easy, efficient implementation of such versatile programming techniques

as background-foreground data processing. The second set of registers consists of six registers with assigned functions. These are the I (Interrupt register), the R (Refresh register), the IX and IY (Index registers), the SP (Stack Pointer), and the PC (Program Counter). The third group consists of two interrupt status flip-flops, plus an additional pair of flip-flops which assists in identifying the interrupt mode at any particular time. Table 1 provides further information on these registers.

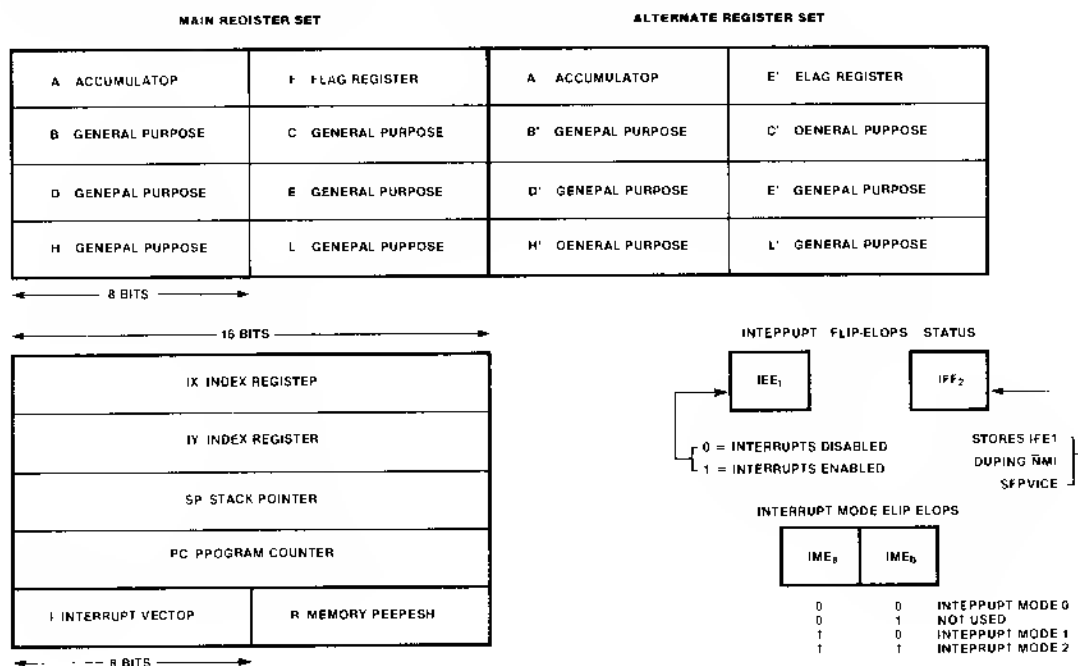

Figure 4. CPU Registers

## INTERRUPTS: GENERAL OPERATION

The CPU accepts two interrupt input signals:  $\overline{\text{NMI}}$  and  $\overline{\text{INT}}$ . The  $\overline{\text{NMI}}$  is a non-maskable interrupt and has the highest priority.  $\overline{\text{INT}}$  is a lower priority interrupt and it requires that interrupts be enabled in software in order to operate.  $\overline{\text{INT}}$  can be connected to multiple peripheral devices in a wired-OR configuration.

The Z80 has a single response mode for interrupt service on the non-maskable interrupt. The maskable interrupt,  $\overline{\text{INT}}$ , has three programmable response modes available. These are:

- Mode 0 — similar to the 8080 microprocessor.
- Mode 1 — Peripheral Interrupt service for use with non-8080/Z80 systems

- Mode 2 — a vectored interrupt scheme, usually daisy-chained, for use with the Z80 Family and compatible peripheral devices.

The CPU services interrupts by sampling the  $\overline{\text{NMI}}$  and  $\overline{\text{INT}}$  signals at the rising edge of the last clock of an instruction. Further interrupt service processing depends upon the type of interrupt that was detected. Details on interrupt responses are shown in the CPU Timing Section.

**Non-Maskable Interrupt ( $\overline{\text{NMI}}$ ).** The nonmaskable interrupt cannot be disabled by program control and therefore will be accepted at all times by the CPU.  $\overline{\text{NMI}}$  is usually reserved for servicing only the highest priority type interrupts, such as that for orderly shutdown after power

## PIN DESCRIPTIONS

**A<sub>0</sub>-A<sub>15</sub>.** *Address Bus* (output, active High, 3-state). A<sub>0</sub>-A<sub>15</sub> form a 16-bit address bus. The Address Bus provides the address for memory data bus exchanges (up to 64K bytes) and for I/O device exchanges.

**BUSACK.** *Bus Acknowledge* (output, active Low). Bus Acknowledge indicates to the requesting device that the CPU address bus, data bus, and control signals MREQ, IORQ, RD, and WR have entered their high-impedance states. The external circuitry can now control these lines.

**BUSREQ.** *Bus Request* (input, active Low). Bus Request has a higher priority than NMI and is always recognized at the end of the current machine cycle. BUSREQ forces the CPU address bus, data bus, and control signals MREQ, IORQ, RD, and WR to go to a high-impedance state so that other devices can control these lines. BUSREQ is normally wired-OR and requires an external pullup for these applications. Extended BUSREQ periods due to extensive DMA operations can prevent the CPU from properly refreshing dynamic RAMs.

**D<sub>0</sub>-D<sub>7</sub>.** *Data Bus* (input/output, active High, 3-state). D<sub>0</sub>-D<sub>7</sub> constitute an 8-bit bidirectional data bus, used for data exchanges with memory and I/O.

**HALT.** *Halt State* (output, active Low). HALT indicates that the CPU has executed a Halt instruction and is awaiting either a nonmaskable or a maskable interrupt (with the mask enabled) before operation can resume. While halted, the CPU executes NOPs to maintain memory refresh.

**INT.** *Interrupt Request* (input, active Low). Interrupt Request is generated by I/O devices. The CPU honors a request at the end of the current instruction if the internal software-controlled interrupt enable flip-flop (IFF) is enabled. INT is normally wired-OR and requires an external pullup for these applications.

**IORQ.** *Input/Output Request* (output, active Low, 3-state). IORQ indicates that the lower half of the address bus holds a valid I/O address for an I/O read or write operation. IORQ is also generated concurrently with M1 during an interrupt acknowledge cycle to indicate that an interrupt response vector can be placed on the data bus.

**M1.** *Machine Cycle One* (output, active Low). M1, together with MREQ, indicates that the current machine cycle is the opcode fetch cycle of an instruction execution. M1, together with IORQ, indicates an interrupt acknowledge cycle.

**MREQ.** *Memory Request* (output, active Low, 3-state). MREQ indicates that the address bus holds a valid address for a memory read or memory write operation.

**NMI.** *Non-Maskable Interrupt* (input, negative edge-triggered). NMI has a higher priority than INT. NMI is always recognized at the end of the current instruction, independent of the status of the interrupt enable flip-flop, and automatically forces the CPU to restart at location 0066H.

**RD.** *Read* (output, active Low, 3-state). RD indicates that the CPU wants to read data from memory or an I/O device. The addressed I/O device or memory should use this signal to gate data onto the CPU data bus.

**RESET.** *Reset* (input, active Low). RESET initializes the CPU as follows: it resets the interrupt enable flip-flop, clears the PC and Registers I and R, and sets the interrupt status to Mode 0. During reset time, the address and data bus go to a high-impedance state, and all control output signals go to the inactive state. Note that RESET must be active for a minimum of three full clock cycles before the reset operation is complete.

**RFSH.** *Refresh* (output, active Low). RFSH, together with MREQ, indicates that the lower seven bits of the system's address bus can be used as a refresh address to the system's dynamic memories.

**WAIT.** *Wait* (input, active Low). WAIT indicates to the CPU that the addressed memory or I/O devices are not ready for a data transfer. The CPU continues to enter a Wait state as long as this signal is active. Extended WAIT periods can prevent the CPU from properly refreshing dynamic memory.

**WR.** *Write* (output, active Low, 3-state). WR indicates that the CPU data bus holds valid data to be stored at the addressed memory or I/O location.

## CPU TIMING

The Z80 CPU executes instructions by proceeding through a specific sequence of operations:

- Memory read or write
- I/O device read or write
- Interrupt acknowledge

The basic clock period is referred to as a T time or cycle, and three or more T cycles make up a machine cycle (M1, M2 or M3 for instance). Machine cycles can be extended either by the CPU automatically inserting one or more Wait states or by the insertion of one or more Wait states by the user.

**Instruction Opcode Fetch.** The CPU places the contents of the Program Counter (PC) on the address bus at the start of the cycle (Figure 5). Approximately one-half clock cycle later,  $\overline{MREQ}$  goes active. When active,  $\overline{RD}$  indicates that the memory data can be enabled onto the CPU data bus.

The CPU samples the  $\overline{WAIT}$  input with the falling edge of clock state  $T_2$ . During clock states  $T_3$  and  $T_4$  of an M1 cycle, dynamic RAM refresh can occur while the CPU starts decoding and executing the instruction. When the Refresh Control signal becomes active, refreshing of dynamic memory can take place.

Figure 5. Instruction Opcode Fetch

**Memory Read or Write Cycles.** Figure 6 shows the timing of memory read or write cycles other than an opcode fetch (M1) cycle. The  $\overline{\text{MREQ}}$  and  $\overline{\text{RD}}$  signals function exactly as in the fetch cycle. In a memory write cycle,  $\overline{\text{MREQ}}$  also

becomes active when the address bus is stable. The  $\overline{\text{WR}}$  line is active when the data bus is stable, so that it can be used directly as an  $\text{R}/\overline{\text{W}}$  pulse to most semiconductor memories.

Figure 6. Memory Read or Write Cycles

**Input or Output Cycles.** Figure 7 shows the timing for an I/O read or I/O write operation. During I/O operations, the CPU automatically inserts a single Wait state ( $T_{WA}$ ). This

extra Wait state allows sufficient time for an I/O port to decode the address from the port address lines.

$T_{WA}$  = One wait cycle automatically inserted by CPU.

**Figure 7. Input or Output Cycles**

**Interrupt Request/Acknowledge Cycle.** The CPU samples the interrupt signal with the rising edge of the last clock cycle at the end of any instruction (Figure 8). When an interrupt is accepted, a special  $\overline{M1}$  cycle is generated.

During this  $\overline{M1}$  cycle,  $\overline{IORQ}$  becomes active (instead of  $\overline{MREQ}$ ) to indicate that the interrupting device can place an 8-bit vector on the data bus. The CPU automatically adds two Wait states to this cycle.

**Non-Maskable Interrupt Request Cycle.**  $\overline{\text{NMI}}$  is sampled at the same time as the maskable interrupt input  $\overline{\text{INT}}$  but has higher priority and cannot be disabled under software control. The subsequent timing is similar to that of a normal

memory read operation except that data put on the bus by the memory is ignored. The CPU instead executes a restart (RST) operation and jumps to the  $\overline{\text{NMI}}$  service routine located at address 0066H (Figure 9).

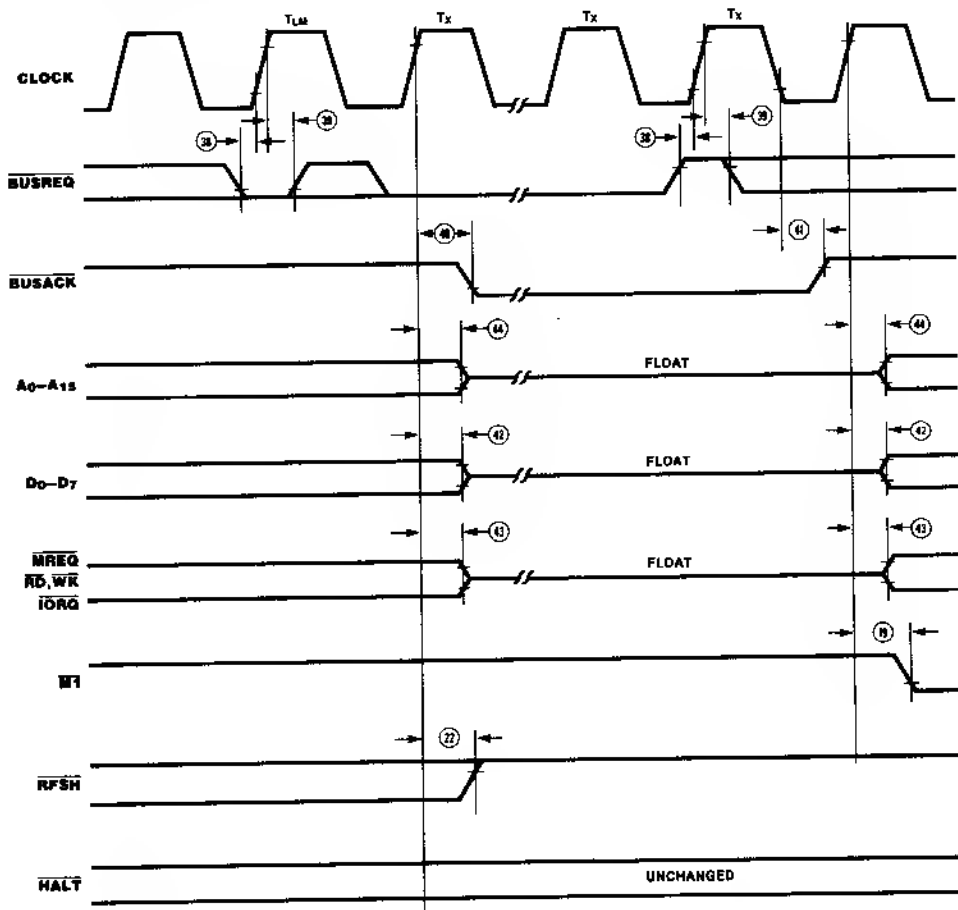

\*Although  $\overline{\text{NMI}}$  is an asynchronous input, to guarantee its being recognized on the following machine cycle,  $\overline{\text{NMI}}$ 's falling edge must occur no later than the rising edge of the clock cycle preceding the last state of any instruction cycle (T<sub>1</sub>).

Figure 9. Non-Maskable Interrupt Request Operation

**Bus Request/Acknowledge Cycle.** The CPU samples BUSREQ with the rising edge of the last clock period of any machine cycle (Figure 10). If BUSREQ is active, the CPU sets its address, data, and MREQ, IORQ, RD, and WR lines

to a high-impedance state with the rising edge of the next clock pulse. At that time, any external device can take control of these lines, usually to transfer data between memory and I/O devices.

NOTES: 1)  $T_{LM}$  = Last state of any M cycle.  
2)  $T_X$  = An arbitrary clock cycle used by requesting device.

**Figure 10. BUS Request/Acknowledge Cycle**

**Halt Acknowledge Cycle.** When the CPU receives a **HALT** instruction, it executes NOP states until either an **INT** or **NMI** input is received. When in the Halt state, the **HALT** output is

active and remains so until an interrupt is received (Figure 11). **INT** will also force a Halt exit.

\*Although **NMI** is an asynchronous input, to guarantee its being recognized on the following machine cycle, **NMI**'s falling edge must occur no later than the rising edge of the clock cycle preceding the last state of any instruction cycle ( $T_1$ ).

Figure 11. Halt Acknowledge

**Reset Cycle.** **RESET** must be active for at least three clock cycles for the CPU to properly accept it. As long as **RESET** remains active, the address and data buses float, and the control outputs are inactive. Once **RESET** goes inactive, two

internal T cycles are consumed before the CPU resumes normal processing operation. **RESET** clears the PC register, so the first opcode fetch will be to location 0000H (Figure 12).

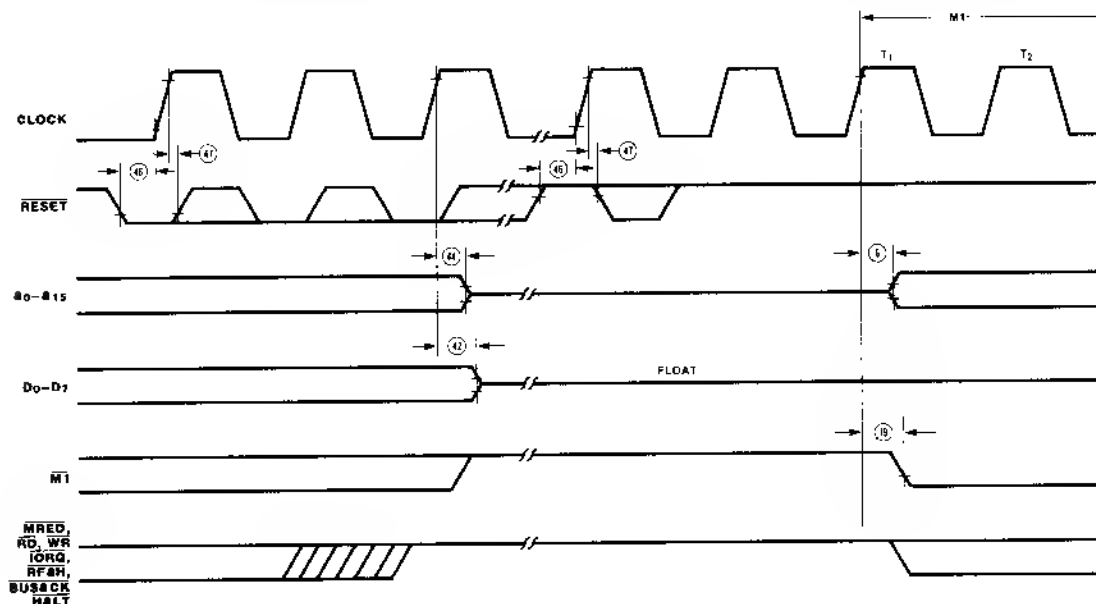

Figure 12. Reset Cycle

**Power-Down mode of operation** (Only applies to CMOS Z80 CPU).

CMOS Z80 CPU supports Power-Down mode of operation.

This mode is also referred to as the "standby mode", and supply current for the CPU goes down as low as 10  $\mu\text{A}$  (Where specified as  $I_{CC2}$ ).

**Power-Down Acknowledge Cycle.** When the clock input to the CPU is stopped at either a High or Low level, the CPU stops its operation and maintains all registers and control signals. However  $I_{CC2}$  (standby supply current) is guaranteed only when the system clock is stopped at a Low

level during  $T_4$  of the machine cycle following the execution of the HALT instruction. The timing diagram for the power-down function when implemented with the HALT instruction, is shown in Figure 13.

Figure 13. Power-Down Acknowledge

**Power-Down Release Cycle.** The system clock must be supplied to the CPU to release the power-down state. When the system clock is supplied to the CLK input, the CPU restarts operations from the point at which the power-down state was implemented. The timing diagrams for the release from power-down mode are shown in Figure 14.

#### NOTES.

- 1) When the external oscillator has been stopped to enter the power-down state, some warm-up time may be required to obtain a stable clock for the release.
- 2) When the HALT instruction is executed to enter the power-down state, the CPU will also enter the Halt state. An interrupt signal (either  $\overline{\text{NMI}}$  or  $\overline{\text{INT}}$ ) or a RESET signal must be applied to the CPU after the system clock is supplied in order to release the power-down state.

## ABSOLUTE MAXIMUM RATINGS

Voltage on $V_{CC}$ with respect to $V_{SS}$ . . . . .	-0.3V to +7V
Voltages on all inputs with respect to $V_{SS}$ . . . . .	-0.3V to $V_{CC}$ + 0.3V
Operating Ambient Temperature . . . . .	See Ordering Information
Storage Temperature . . . . .	-65°C to +150°C

Stresses greater than those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; operation of the device at any condition above those indicated in the operational sections of these specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## STANDARD TEST CONDITIONS

The DC Characteristics and capacitance sections below apply for the following standard test conditions, unless otherwise noted. All voltages are referenced to GND (0V). Positive current flows into the referenced pin.

Available operating temperature ranges are:

### ■ S = 0°C to +70°C

#### Voltage Supply Range:

NMOS: +4.75V  $\leq V_{CC} \leq$  +5.25V

CMOS: +4.50V  $\leq V_{CC} \leq$  +5.50V

### ■ E = -40°C to 100°C, +4.50V $\leq V_{CC} \leq$ +5.50V

All ac parameters assume a load capacitance of 100 pF. Add 10 ns delay for each 50 pF increase in load up to a maximum of 200 pF for the data bus and 100 pF for address and control lines. AC timing measurements are referenced to 1.5 volts (except for clock, which is referenced to the 10% and 90% points).

The Ordering Information section lists temperature ranges and product numbers. Package drawings are in the Package Information section. Refer to the Literature List for additional documentation.

## DC CHARACTERISTICS (Z84C00/CMOS Z80 CPU)

Symbol	Parameter	Min	Max	Unit	Condition
$V_{ILC}$	Clock Input Low Voltage	-0.3	0.45	V

V<sub>IHC</sub> = V<sub>CC</sub> - 0.6 V  
V<sub>ILC</sub> = 0.45 V

Float = ±0.5 V

Figure 1. Address Delay Characteristics  
(Parameter 6)

## DC CHARACTERISTICS (Z8400/NMOS Z80 CPU)

All parameters are tested unless otherwise noted.

Symbol	Parameter	Min	Max	Unit	Test Condition
$V_{ILC}$	Clock Input Low Voltage	-0.3	0.45	V	
$V_{IHC}$	Clock Input High Voltage	$V_{CC} - .6$	$V_{CC} + .3$	V	
$V_{IL}$	Input Low Voltage	-0.3	0.8	V	
$V_{IH}$	Input High Voltage	2.0 <sup>1</sup>	$V_{CC}$	V	
$V_{OL}$	Output Low Voltage		0.4	V	$I_{OL} = 2.0 \text{ mA}$
$V_{OH}$	Output High Voltage	2.4 <sup>1</sup>		V	$I_{OH} = -250 \mu\text{A}$
$I_{CC}$	Power Supply Current		200	mA	Note 3
$I_{LI}$	Input Leakage Current		10	$\mu\text{A}$	$V_{IN} = 0 \text{ to } V_{CC}$
$I_{LO}$	3-State Output Leakage Current in Float	-10	10 <sup>2</sup>	$\mu\text{A}$	$V_{OUT} = 0.4 \text{ to } V_{CC}$

1 For military grade parts, refer to the Z80 Military Electrical Specification

2  $A_{15}$ ,  $A_0$ ,  $D_7$ - $D_0$ ,  $MREQ$ ,  $IORQ$ ,  $RD$ , and  $WR$

3 Measurements made with outputs floating

## CAPACITANCE

Guaranteed by design and characterization.

Symbol	Parameter	Min	Max	Unit
$C_{CLOCK}$	Clock Capacitance		35	pf
$C_{IN}$	Input Capacitance		5	pt
$C_{OUT}$	Output Capacitance		15	pt

### NOTES

$T_A = 25^\circ\text{C}$ ,  $f = 1 \text{ MHz}$

Unmeasured pins returned to ground

# AC CHARACTERISTICS† (Z8400/NMOS Z80 CPU)

Number	Symbol	Parameter	Z0840004		Z0840006		Z0840008	
			Min	Max	Min	Max	Min	Max
1	TcC	Clock Cycle Time	250*		162*		125*
